$\mathbf{Q}\mathbf{1}$

a)

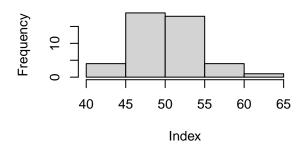

```
Data = read.table("PatientSatisfaction.txt", col.names=c("Satisfaction", "Age", "Severity", "Anxiety")
layout(matrix(c(1,1,2,3), 2, 2, byrow = TRUE))
hist(Data$Age,
 main="Patient Age",
 xlab="Age in Years",
  xlim=c(20,55),
hist(Data$Severity,
 main="Severity of Illness",
 xlab="Index",
  xlim=c(40,65),
hist(Data$Anxiety,
  main="Anxiety Level",
  xlab="Index",
  xlim=c(1.5,3),
  breaks=c(1,1.25,1.5,1.75,2,2.25,2.5,2.75,3)
)
```

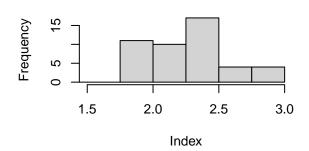

Patient Age

Severity of Illness

Anxiety Level

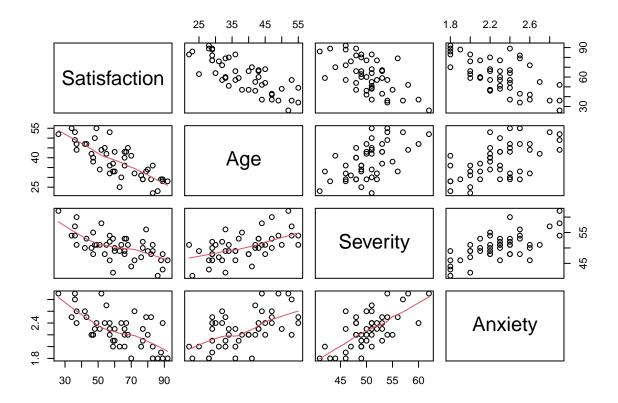

It is noteworthy that it seems all 3 plots are normally distributed.

b)

```
# scatter plot matrix
pairs(~Satisfaction +Age + Severity+ Anxiety, data = Data, lower.panel = panel.smooth)
```

cor(cbind(Data\$Age, Data\$Severity, Data\$Anxiety))

```
## [,1] [,2] [,3]
## [1,] 1.0000000 0.5679505 0.5696775
## [2,] 0.5679505 1.0000000 0.6705287
## [3,] 0.5696775 0.6705287 1.0000000
```

Our scatter plot matrix shows that all 3 predictor value are positively correlated with each other, however, all 3 are negatively correlated with patient satisfaction.

Since none of the correlations between the predictor variables exceed 0.7, the correlations are not extreme enough to raise any concerns of multicollinearity.

c)

```
fit = lm(Satisfaction ~ Age + Severity + Anxiety, data = Data)
summary(fit)

## F-statistic: 30.05 on 3 and 42 DF, p-value: 1.542e-10
```

The estimated regression function is

$$Y = 158.4912517 + -1.1416118 \cdot X_1 + -0.4420043 \cdot X_2 + -13.4701632 \cdot X_3$$

 $\hat{\beta}_2$ is interpreted as, controlling for X_1 and X_3 , a 1-unit increase in X_2 corresponds to a predicted increase of -1.1416118 in patient satisfaction.

 \mathbf{d})

Fstat

$$H_0: \hat{\beta}_1 = \hat{\beta}_2 = \hat{\beta}_3 = 0, \quad H_a: \hat{\beta}_1 \neq 0 \lor \hat{\beta}_2 \neq 0 \lor \hat{\beta}_3 \neq 0$$

Decision rule: reject if

P Value =
$$pf(F, 3, n - p') < \alpha$$

then we reject H_0

```
alpha = 0.10

Radj
```

[1] 0.6594939

1 69.01029 51.50965 86.51092

The R^2 value of 0.6821943 means that $100 \cdot (0.6821943)\%$ of the data fit the regression model. Furthermore, since the adjusted R^2 value is close to R^2 , we can say most prediction variables are having an effect on predictions.

f)

```
#fit
pred = predict(fit, data.frame(Age = 35, Severity = 45, Anxiety = 2.2 ) , interval="prediction", level
pred
## fit lwr upr
```

I am 90% confident that a future patient with age 35, severity of illness 45, and anxiety level 2.2 will have a patient satisfaction within the range

                               P value = 1.0660575 \times 10^{-7} < \alpha = 0.05
we reject H_0.
```

d)

The model I would choose for this data is the full model, with all dummy variables and interactions. This is because we rejected that the interactions have no effect on slope, so we know the interactions have some significant effects on the model. So we want to use the full model to capture that.

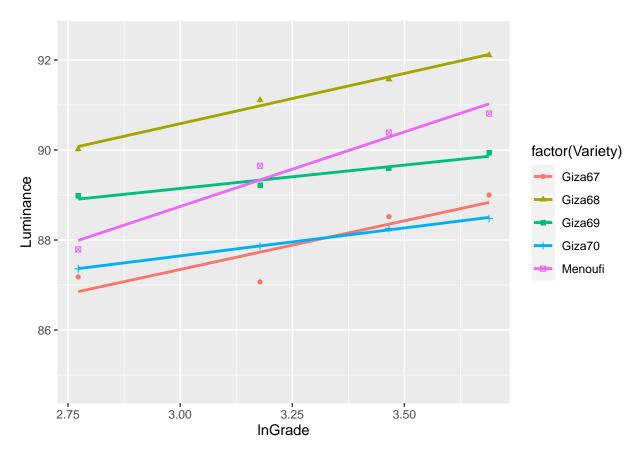

e)

```
if(!require("ggplot2")) install.packages("ggplot2")
```

Loading required package: ggplot2

```
library(ggplot2)
ggplot(data=Data, aes(x=lnGrade, y=Luminance, color= factor(Variety), shape=factor(Variety))) + geom_po
```

'geom_smooth()' using formula 'y ~ x'

Normality:

```
p = shapiro.test(fullFit$residuals)$p.value
```

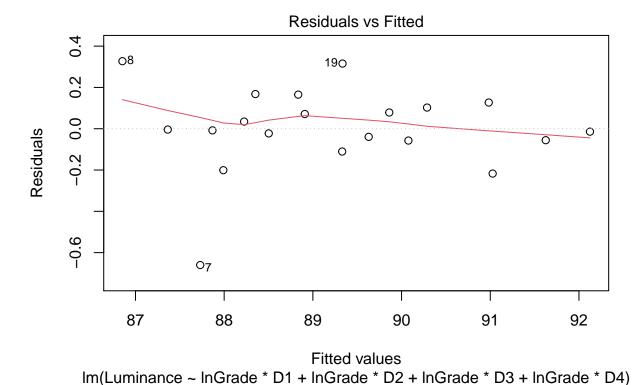

since

P value =
$$0.0190846 < \alpha = 0.05$$

we reject that this fit satisfies the normality assumption.

Equal Variance :

```
plot(fullFit, which=1)
```

Visually, aside from 1 outlier at (87.7, -0.66), the residuals are uniformly distributed, and Equal Variance holds.

Linearity:

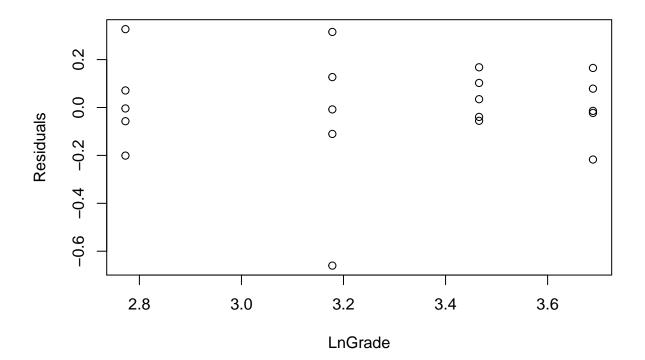

summary(fullFit)

```

## F-statistic: 52.82 on 9 and 10 DF, p-value: 2.986e-07
```

As we can see from the P values, we reject that any of the 5 slopes are 0. Also, from the graph we can confidently see that there is a linear relationship between luminance and lnGrade for all 5 categories. from these 2 observations, we can say our model satisfies linearity.

Independent/uncorrelated error terms:

From this plot, I visually access that there is no major deviate patterns, therefor Independent/uncorrelated error terms is satisfied.

Question 5.

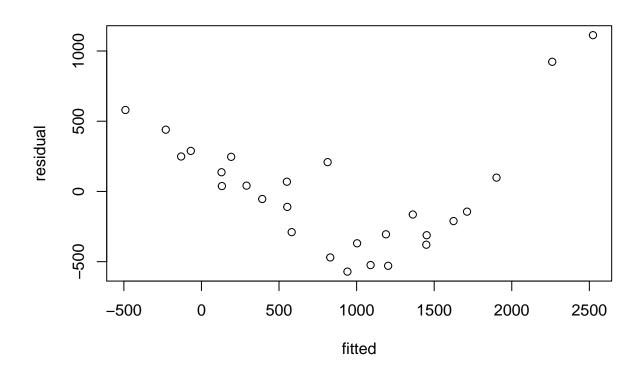

plot(x=fitted, y=residual)

```
WoolStrengthData <- read.table("StrengthWool.txt", header = TRUE)
```

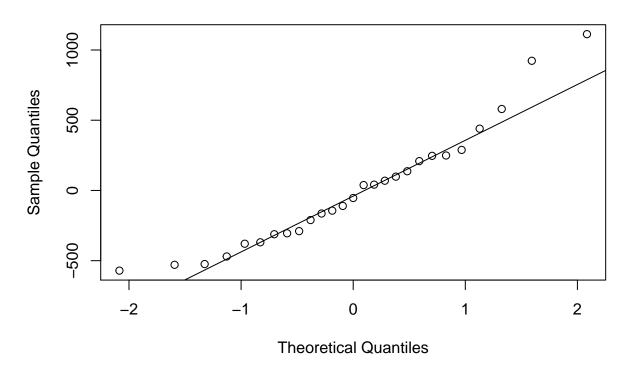

Part a.

Fit a linear model with just main effects for the three class variables and show that this is not a good fit to the data

```
Cycles = WoolStrengthData$Cycles
lenCut \leftarrow cut(WoolStrengthData$Len, breaks=c(0,250, 300, 350), labels = c("250", "300", "350"))
ampCut <- cut(WoolStrengthData$Amp, breaks=c(0,8,9,10), labels = c("8", "9", "10"))</pre>
loadCut <- cut(WoolStrengthData$Load, breaks=c(0,40,45,50), labels=c("40", "45", "50"))</pre>
fit <- lm(Cycles ~ lenCut + ampCut + loadCut, data = WoolStrengthData)</pre>

residual <- fit$residuals
fitted <- fit$fitted.values
```

qqnorm(residual)
qqline(residual)

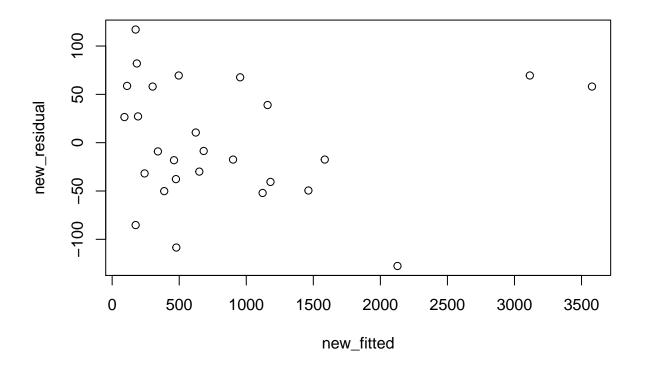

If we look at the plot of the Residual Plot as well as the QQ Plot of the model, we can see that this model is not a good fit to the data, where the QQ Plot shows many points not following the linear line, as well as the curved shape in the residual plot not showing signs of a good fit.

#5.b)

If we look at the new residual plot of the new model, we can see that this model is a better fit to the data, as we can see that the variance is linear around 0 but does not have constant variance. Hence, the model which considers all the interactions between pairs of the class variables is a better model for fitting the data.

```

We can see that the result of this is very similar to that of part c. However, it is not a significant change in terms of deciding a better fit, and we can use F-test. Since the p-value of F-test is 0.1325 > 0.05, With 95% confidence we cannot reject H0 as there is evidence that the interaction terms have no effect on the model with transformations
